How to read

```
\begin{array}{ll} 800000 & kinds \\ 008000 & types \ (constructors) \\ 000080 & terms \end{array}
```

Issues

Issue 1: Algorithmic rules are not "officially" algorithmic

Since we are going all out to Do It Right^{\top M}, it should be noted that the declarative/algorithmic bifurcation is not complete with :: $(\Delta; \Phi \vdash \tau :: \kappa)$.

For example, kind analysis is premissed on $\lesssim (\Delta; \Phi \vdash \kappa_1 \lesssim \kappa_2)$ at KAASubsume, which is itself premissed on $\equiv (\Delta; \Phi \vdash \tau_1 \equiv \tau_2)$ at KCRespectEquiv, which is itself premissed on :: $(\Delta; \Phi \vdash \tau :: \kappa)$ at KCESingEquiv.

Explicitly algorithmic counterparts to \lesssim and \equiv need to be defined. Suggested notation: \lesssim and \iff (faintly reminiscent of Stone and Harper). A declarative most specific kind (up to equivalence) would also be useful; *principal kinds* (\uparrow) a la Stone and Harper.

Issue 2: A $t::\kappa \in \Phi \implies t::\mathbf{S}(t)$ (like) rule is problematic

When $\forall \tau. \Delta; \Phi \vdash \tau :: \kappa \implies \Delta; \Phi \vdash \tau :: \mathsf{Type}$, as is now, this is fine (except for improperly (non)contexted holes $\forall \tau. \vdash \tau :: \mathsf{Type}$ I would think). But in the presence of non Type kinds, this rule no longer conveys the correct meaning (intuitively speaking).

For example, if we redefined $\mathtt{list}(\tau)$ to be a type constructor proper instead of a builtin type schema, such that $\mathtt{List}::\mathtt{Type} \to \mathtt{Type} \in \Phi \vdash \mathtt{List}::\mathtt{Type} \to \mathtt{Type}$, with the following definitions, data $\mathtt{List} \ \alpha = \mathtt{Nil} \mid \mathtt{Cons} \ \alpha \ (\mathtt{List} \ \alpha)$

```
{\tt type} \; {\tt T} = {\tt List}
```

We would expect the following to be derivable:

```
\cdot; List::Type \to Type, T::S<sub>Type\toType</sub>(List) := \Pi_{t::Type}.S(List t) \vdash T \equiv List as well as:
```

- \cdot ; List::Type \to Type, T::S_{Type \to Type}(List) := $\Pi_{t::Type}$.S(List t), t_{α} ::Type \vdash T $t_{\alpha} \equiv$ List t_{α} but we would not want:
- $\cdot ; \mathit{List} :: \texttt{Type} \rightarrow \texttt{Type}, T :: \texttt{S}_{\texttt{Type} \rightarrow \texttt{Type}}(\texttt{List}) := \Pi_{t :: \texttt{Type}}. \texttt{S}(\texttt{List}\ t) \vdash \texttt{T} :: \texttt{S}(\texttt{T})$

However as the notation suggests:

 \cdot ; List::Type \to Type, $T::S_{\texttt{Type} \to \texttt{Type}}(\texttt{List}) := \Pi_{t::\texttt{Type}}.S(\texttt{List}\ t) \vdash T::S_{\texttt{S_{\texttt{Type}} \to \texttt{Type}}(\texttt{List})}(\texttt{T})$ is expected to be derivable.

It is not possible to model this behavior without higher order singletons and dependent function kinds. Thankfully, Stone and Harper showed that HOSingletons are definable in terms of "vanilla" singletons. Thus, we do not need to add HOSingletons to the object language itself—only to the metalangauge. HOSingletons should make the metatheory proofs more general, even without considering type constructors. See Attachment 2 for an example. The concern, as raised by cryus- is how HOSingletons and holes should interact; And with type constructors, how dependent kinds and holes should interact (gradual dependent types?? Eremondi, Tanter, Garcia 2019??) (just leaving breadcrumbs; haven't read more than 4 sentences)

Not Issues -- but worth mentioning

Nibwm 1: In the presence of higher order types/type constructors, there exists a more nuanced notion of type equivalence (extensionality) in which equivalence depends on the kind at which the types are compared

Without "real" subkinding, examples are a bit more contrived.

From Stone and Harper (2006):

$$\vdash \lambda t :: \texttt{Type}.t \stackrel{\texttt{S(Int)} \to \texttt{Type}}{\equiv} \lambda t :: \texttt{Type}. \texttt{Int}$$

should be derivable but

$$\vdash \lambda t :: \texttt{Type}.t \stackrel{\texttt{Type} \to \texttt{Type}}{\equiv} \lambda t :: \texttt{Type}. \texttt{Int}$$

should not, where $\vdash \mathsf{Type} \to \mathsf{Type} \lesssim \mathtt{S}(\mathsf{Int}) \to \mathsf{Type}$ Interestingly

$$\vdash \lambda t :: \texttt{Type}.t \stackrel{\texttt{S}(\texttt{Int}) \to \texttt{S}(\texttt{Int})}{\equiv} \lambda t :: \texttt{Type}. \texttt{Int}$$

should also be derivable, where $\vdash S(Int) \rightarrow S(Int) \lesssim S(Int) \rightarrow Type$

With "real" subkinding, this behavior is more serious.

From Aspinall (1995), using singleton types and $Nat \leq Int$ ("real" subtyping):

$$\vdash \lambda x:Int.if x > 0 then x else 2 * x \stackrel{\text{Nat} \to Int}{\equiv} \lambda x:Int.x$$

should be derivable but

$$\vdash \lambda x:Int.if x \ge 0 then x else 2*x \stackrel{Int \to Int}{\equiv} \lambda x:Int.x$$

should not.

I do not believe this more nuanced view of equality buys us anything.

Attachments

Theorem 1 (Well-Kinded Elaboration)

(1) If
$$\Phi \vdash \hat{\tau} \Rightarrow \kappa \leadsto \tau \dashv \Delta \ then \ \Delta; \Phi \vdash \tau \Rightarrow \kappa$$

(2) If
$$\Phi \vdash \hat{\tau} \Leftarrow \kappa \leadsto \tau \dashv \Delta \ then \ \Delta; \Phi \vdash \tau \Leftarrow \kappa$$

This is like the Typed Elaboration theorem in the POPL19 paper.

Theorem 2 (Elaborability)

- (1) $\exists \Delta$ s.t. if Δ ; $\Phi \vdash \tau \Rightarrow \kappa$ then $\exists \hat{\tau}$ such that $\Phi \vdash \hat{\tau} \Rightarrow \kappa \leadsto \tau \dashv \Delta$
- (2) $\exists \Delta$ s.t. if Δ ; $\Phi \vdash \tau \Leftarrow \kappa$ then $\exists \hat{\tau}$ such that $\Phi \vdash \hat{\tau} \Leftarrow \kappa \leadsto \tau \dashv \Delta$

This is similar but a little different from Elaborability theorem in the POPL19 paper. Choose the Δ that is emitted from elaboration and then there's an $\hat{\tau}$ that elaborates to any of the τ forms. Elaborability and Well-Kinded Elaboration implies we can just rely on the elaboration forms for the premises of any rules that demand kind synthesis/analysis.

Theorem 3 (Type Elaboration Unicity)

(1) If
$$\Phi \vdash \hat{\tau} \Rightarrow \kappa_1 \rightsquigarrow \tau_1 \dashv \Delta_1$$
 and $\Phi \vdash \hat{\tau} \Rightarrow \kappa_2 \rightsquigarrow \tau_2 \dashv \Delta_2$ then $\kappa_1 = \kappa_2$, $\tau_1 = \tau_2$, $\Delta_1 = \Delta_2$

(2) If
$$\Phi \vdash \hat{\tau} \Leftarrow \kappa \leadsto \tau_1 \dashv \Delta_1$$
 and $\Phi \vdash \hat{\tau} \Leftarrow \kappa \leadsto \tau_2 \dashv \Delta_2$ then $\tau_1 = \tau_2$, $\Delta_1 = \Delta_2$

This is like the Elaboration Unicity theorem in the POPL19 paper.

Theorem 4 (Kind Synthesis Precision)

If Δ ; $\Phi \vdash \tau \Rightarrow \kappa_1$ and Δ ; $\Phi \vdash \tau \Leftarrow \kappa_2$ then Δ ; $\Phi \vdash \kappa_1 \lesssim \kappa_2$

Kind Synthesis Precision says that synthesis finds the most precise kappa possible for a given input type. This is somewhat trivial, but interesting to note because it means we can expect singletons wherever possible.

Theorem 5.1 (Kind Analysis Soundness)
If Ajett = K then Ajett:: k

Theorem S.Z (Kind Analysis Completeners)
IF DJEHT:: K then DJEHT & K

5.1 Industra on complexity

```
Kind Analysis Soundness in 9-type-aliases
     Attachment 2
If \Delta; \Phi \vdash \tau \Leftarrow \kappa, then \Delta; \Phi \vdash \tau :: \kappa
Without HOSingletons:
        base case \tau = t:
                (easy) case KAVar:
                       t::\kappa_1 \in \Phi \text{ and } \Delta; \Phi \vdash \kappa_1 \lesssim \kappa
                       Thus by 43.2b, \Delta; \Phi \vdash t :: \kappa_1
                       By 43.2d, \Delta; \Phi \vdash t :: \kappa
                       Thus \Delta; \Phi \vdash \tau :: \kappa
                (hard) case KAASubsume:
                       \Delta; \Phi \vdash \tau \Rightarrow \kappa_1 \text{ and } \Delta; \Phi \vdash \kappa_1 \lesssim \kappa
                       By KSVar, t:: \kappa_2 \in \Phi and \kappa_1 = S(t)
                       Thus, \Delta; \Phi \vdash S(t) \lesssim \kappa
                        wts \Delta; \Phi \vdash t::S(t), requires \Delta; \Phi \vdash t::Type
                        can show \Delta; \Phi \vdash t::Type by exhaustive syntactic case + subsumption
                        (\forall \kappa_2.\Delta; \Phi \vdash \kappa_2 \lesssim \mathsf{Type})
With HOSingletons:
        base case \tau = t:
                (easy) case KAVar:
```

same

(hard) case KAASubsume:

And, Δ ; $\Phi \vdash t :: \kappa_2$ Thus Δ ; $\Phi \vdash t :: \mathbf{S}_{\kappa_2}(t)$ Thus, Δ ; $\Phi \vdash t :: \kappa$ Thus, Δ ; $\Phi \vdash \tau :: \kappa$

Thus, $\Delta; \Phi \vdash S_{\kappa_2}(t) \lesssim \kappa$

 $\Delta; \Phi \vdash \tau \Rightarrow \kappa_1 \text{ and } \Delta; \Phi \vdash \kappa_1 \lesssim \kappa$ By KSVar, $t :: \kappa_2 \in \Phi \text{ and } \kappa_1 = S_{\kappa_2}(t)$
